

LISTING OF CLAIMS

This listing of claims replaces all prior versions and listings of claims in the patent application.

Claim 1 (currently amended): An integrally molded surface fastener of synthetic resin in which a number of fine engaging elements, which engage/disengage a mating pile piece, are molded integrally on a surface of a flat base member, wherein

each engaging element comprises a pillar portion having a predetermined height and an engaging head composed of first and second engaging portions, which extend from a top end of the pillar portion along the surface of the base member in a first direction (x) and in a second direction (y) different from the first direction, and

the first and second engaging portions have different shapes,

the pillar portion includes a first pillar portion and a second pillar portion which have a rectangular section and are formed integrally such that they intersect each other, the first engaging portion has a flat wing-like thin plate shape extending in a long side direction of the first pillar portion from a top end of the first pillar portion,

the second engaging portion has a hook shape extending in a long side direction of the second pillar portion from a top end of the second pillar portion,

there is a difference in distance between a distance from the surface of the base member to the front end of the first engaging portion and a distance to the front end of the second engaging portion, and

the second engaging portion is formed in a lower height than the first engaging portion.

Claims 2 and 3 (cancelled).

Claim 4 (currently amended): The integrally molded surface fastener according to ~~claim 2~~ claim 1, wherein the second engaging portion is constituted of ~~one or more~~ engaging pieces which substantially intersect with the first engaging portion at right angle across the top end of the pillar portion and extend in opposite directions each other.

Claim 5 (currently amended): The integrally molded surface fastener according to claim 1 ~~or 2~~, wherein the second engaging portion is constituted of a hook piece and a front end of which is curved toward the base member.

Claim 6 (previously presented): The integrally molded surface fastener according to claim 1, wherein the pillar portion has a horizontal section which intersects with the first direction (x) and the second direction (y) of the first and second engaging portions in a same direction.

Claim 7 (currently amended): The integrally molded surface fastener according to claim 1 ~~or 2~~, wherein a central portion of a top face of the engaging head is slightly dented.

Claim 8 (cancelled).

Claim 9 (currently amended): The integrally molded surface fastener according to claim 1 ~~or 2~~, wherein the first engaging portion is disposed perpendicularly to a molding direction of the base member while the second engaging portion is disposed in parallel to ~~the~~ a molding direction of the base member.

Claim 10 (withdrawn): A method of production for the integrally molded surface fastener according to claim 1, comprising:

rotating a cylindrical drum in one direction, the cylindrical drum having a number of preliminarily molded element molding cavities each composed of a main cavity which is open in a circumferential face and extends linearly up to a predetermined depth and a second engaging portion molding cavity which is not open in the circumferential face and is branched from halfway of the main cavity and extends in a molding direction or in a lateral direction with respect thereto;

injecting molten resin continuously to the circumferential face of the cylindrical drum, molding the base member along the circumferential face while molding a number of preliminarily molded elements on a back side of the base member such that they erect upright;

peeling a belt-like preliminarily molded surface fastener from the circumferential face of the cylindrical drum, the preliminarily molded surface fastener having the preliminarily molded elements on the base member which moves carried by the circumferential face of the rotating cylindrical drum;

feeding the preliminarily molded surface fastener peeled continuously to a with-heat pressing portion; and

pressing at least a preliminarily molded first engaging portion erected linearly of the preliminarily molded elements erected integrally from the surface of the base member of the carried preliminarily molded surface fastener with heat, melting and deforming into a flat wing-like thin plate so as to mold the first engaging portion successively.

Claim 11 (withdrawn): The method of continuous production for the integrally molded surface fastener according to claim 10, further comprising:

melting and deforming the preliminarily molded first engaging portion into the flat wing-like thin plate by pressing the with-heat pressing portion with heat; and

melting and deforming a top end of a preliminarily molded second engaging portion at a time.

Claim 12 (withdrawn): A continuous production device for the integrally molded surface fastener according to claim 1 comprising:

a cylindrical drum rotating in one direction and having a number of preliminarily molded element molding cavities composed of a main cavity which is open in a circumferential face and extends up to a predetermined depth and a second engaging portion molding cavity which is branched from halfway of the main cavity and extends in a molding direction;

a continuous injecting unit which injects molten resin continuously to the circumferential face of the cylindrical drum so as to mold the base member along the circumferential face, and molds a number of preliminarily molded elements on a back side of the base member such that they are erected upright;

a take-up roller for peeling a belt-like preliminarily molded surface fastener from the circumferential face of the cylindrical drum continuously, the preliminarily molded surface

fastener having the preliminarily molded elements on the base member which moves carried by the circumferential face of the rotating cylindrical drum; and

a with-heat pressing portion which presses with heat at least a preliminarily molded head erected linearly of the preliminarily molded elements erected integrally from the surface of the base member of the peeled preliminarily molded surface fastener so as to melt and deform into a wing-like thin plate to mold the first engaging portion successively.

Claim 13 (withdrawn): The continuous production device according to claim 12, wherein the with-heat pressing portion comprises an internal heating unit containing a carrying face for the preliminarily molded surface fastener and a rotation roll containing a rotation shaft which is included in a plane above and in parallel to the carrying face and extends in a direction perpendicular to a feeding direction of the preliminarily molded surface fastener, and

a gap between a bottom end position of the heating rotation roll and the carrying face is set smaller than a dimension gained by adding a setting dimension in a vertical direction of the engaging head to a sum of dimensions in a vertical direction of the base member and the pillar portion.

Claim 14 (withdrawn): The continuous production device according to claim 12, wherein the with-heat pressing portion comprises a carrying face for the preliminarily molded surface fastener and is disposed above the carrying face, and further comprises a with-heat pressing member having an inclined face in which a gap between a bottom face thereof and the carrying face decreases gradually, and

a gap of a narrowest portion between the carrying face and the inclined face is smaller than a dimension gained by adding a setting dimension in a vertical direction of the engaging head to a sum of the dimensions in a vertical direction of the base member and the pillar portion.
